Scala basics 2

In this session we'll deepen our knowledge of pattern matching & recursion!

Pattern matching

Pattern matching is a technique used in scala (and other languages) to compare values against shapes and conditions. You can think of it like a more powerful `switch` statement.

Pattern matching

```
val a: Int = 3

a match {
  case 3 => "it's three!"
  case _ => "it's not three!"
}
```

Exhaustivity

Scala's pattern matching has an exhaustivity checker. This means that the compiler will warn if we forget to match against one of the cases.

```
sealed trait Color
case object Blue extends Color
case object Red extends Color
case object Green extends Color
case class Other(name: String) extends Color
```

Exhaustivity

```
scala> val color: Color = Blue
color: Color = Blue

scala> color match {
     |   case Blue => println("it's blue!")
     |   case Other(x) => println(s"it's $x!")
     | }
<console>:17: warning: match may not be exhaustive.
It would fail on the following inputs: Green, Red
       color match {
       ^
it's blue!
```

Destructuring

Destructuring allows us to query inner parts of an ADT

```
sealed trait Vehicle
case class Car(
  brand: String, model: String, color: Color
) extends Vehicle
case class Plane(
  brand: String, model: String, wingSpan: Int
) extends Vehicle
```

Destructuring

```
val vehicle: Vehicle = Car("Honda", "Accord", Red)
```

Destructuring

```
vehicle match {
  case Car(brand, model, Red) =>
    s"it's a red $brand $model"
  case Car(brand, model, Blue) =>
    s"it's a red $brand $model"
  case Car(brand, model, Other(colorName)) =>
    s"it's a $colorName $brand $model"
  case Plane(brand, model, wingSpan) =>
    s"it's a $brand $model with $wingSpan meter of wing spa
}
```

Guards

Guards are boolean conditions we want to check while pattern matching.

```
val plane: Vehicle = Plane("Boeing", "747", 47)

plane match {
  case Plane(brand, model, wingSpan) if wingSpan > 40 =>
    s"it's a big $brand $model"
  case Plane(brand, model, wingSpan) if wingSpan <= 40 =>
    s"it's a small $brand $model"
  case _ => s"it's not a plane..."
}
```

Recursion

Recursion happens when a function calls itself. It's the solution we use in functional programming to the problems for which OOP uses loops.

Notice: we will not deal with tail recursion in this section

Recursion

Fibonacci sequence

Fibonacci sequence is an infinite in which every number is defined by summing the two previous numbers.

Recursion

Fibonacci in Python (strawman :D)

```
def fib(num):
    a, b, temp = (1, 0, 0)
    while(num >= 0):
        temp = a
        a = a+b
        b = temp
        num = num - 1
    return b
```

Recursion

Fibonacci in Scala

```
def fib(num: Int): Int = num match {
  case 0 => 1
  case 1 => 1
  case x => fib(x - 1) + fib(x - 2)
}
```

Recursion

Recursion is tightly coupled to pattern matching and algebraic data types.

Recursion

Let's declare a linked list in scala.

```
sealed trait List[A]
case class Empty[A]() extends List[A]
case class NonEmpty[A](
  head: A,
  tail: List[A]
) extends List[A]
```

Recursion

This is how we could create instances of this list.

```
val three = NonEmpty(
  1,
  NonEmpty(
    2,
    NonEmpty(
      3,
      Empty())))
```

Recursion

length

```
def length[A](l: List[A]): Int =
  l match {
    case Empty() => 0
    case NonEmpty(x, xs) => 1 + length(xs)
  }

length(three)
```

Recursion

sum

```
def sum(list: List[Int]): Int =
  list match {
    case Empty() => 0
    case NonEmpty(x, xs) => x + sum(xs)
  }
```

Exercise 2.1

Implement a generic binary tree data structure.

Exercise 2.1

Implement a generic binary tree data structure.

Solution

```
sealed trait Tree[A]
case class Empty[A]() extends Tree[A]
case class Node[A](
  l: Tree[A],
  a: A,
  r: Tree[A]
) extends Tree[A]
```

Exercise 2.2

create a function to calculate the height of a tree.

Exercise 2.2

create a function to calculate the height of a tree.

Solution

```
def height[A](tree: Tree[A]): Int = tree match {
  case Empty() => 0
  case Node(l, _, r) => 1 + (height(l).max(height(r)))
}
```

Exercise 2.3

Create a function that sums all the leaves of an Int tree.

Exercise 2.3

Create a function that sums all the leaves of an Int tree.

Solution

```
def sum(tree: Tree[Int]): Int = tree match {
  case Empty() => 0
  case Node(l, x, r) => x + sum(l) + sum(r)
}
```

Exercise 2.4

Create a function that counts all the leaves in a tree

Exercise 2.4

Create a function that counts all the leaves in a tree

Solution

```
def count[A](tree: Tree[A]): Int = tree match {
  case Empty() => 0
  case Node(l, _, r) => 1 + count(l) + count(r)
}
```

Exercise 2.5

Create a function that transforms each element in a tree into it's string representation

Exercise 2.5

Create a function that transforms each element in a tree into it's string representation

Solution

```
def toStringNodes(tree: Tree[Int]): Tree[String] = tree mat
  case Empty() => Empty()
  case Node(l, x, r) => Node(
    toStringNodes(l),
    x.toString,
    toStringNodes(r))
}
```

Exercise 2.6

Create a function that squares all elements in an Int tree

Exercise 2.6

Create a function that squares all elements in an Int tree

Solution

```
def squared(tree: Tree[Int]): Tree[Int] = tree match {
  case Empty() => Empty()
  case Node(l, x, r) => Node(
    squared(l),
    x * x,
    squared(r))
}
```

Postscript: variance

Scala allows us to express the variance of generic types. They can either be invariant (all the generics we've seen are invariant), covariant, or contravariant.

Postscript: variance

Covariance

We express Covariance adding a + sign before the generic parameter name.

Postscript: variance

Covariance

Let `List` be a type constructor declared as:

```
trait List[+A]
```

If we have two types `Foo` and `Bar`,and `Foo` is a subtype of `Bar`, since `List` is covariant, `List[Foo]` is a subtype of `List[Bar]`.

Postscript: variance

Contravariance

Contravariance is similar to covariance, but the inverse. If we declare a type constructor as contravariant:

```
trait Logger[-A]
```

We mean that, for two types `Foo` and `Bar` if `Foo` is a subtype of `Bar`, then `List[Bar]` is a subtype of `List[Foo]`

Postscript: variance

Contravariance

```
class Vehicle
class Car extends Vehicle

def carLogger: Logger[Car] = null
def vehicleLogger: Logger[Vehicle] = null

def logCar(logger: Logger[Car]) = null

logCar(carLogger)
logCar(vehicleLogger)
```

Postscript: variance

As a final note, try to be very careful of when you use variance. It might get out of hand quickly, and when you get to the functional libraries such as cats or scalaz, it's difficult to make it fit.
